

Goal: ground state search for infinite system while exploiting translational invariance.

We will use Vidal's  $\lambda$  notation [see Section 2], but the strategy can be expressed in other notations, too.

Basic idea: 'imaginary time evolution':  $\lim_{\beta \rightarrow \infty} e^{-\beta \hat{H}} |\psi\rangle \propto |g\rangle$  (1)

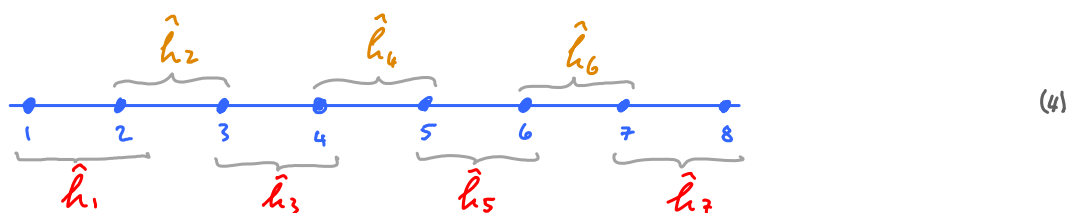

Reason: high-energy states die out quickly (if ground state is gapped):

$$e^{-\beta \hat{H}} = \sum_{\alpha} e^{-\beta E_{\alpha}} |\alpha\rangle \langle \alpha| \xrightarrow{\beta \rightarrow \infty} \underbrace{e^{-\beta E_g}}_{\text{complete set of energy eigenstates}} \underbrace{|g\rangle \langle g|}_{\text{projector onto ground state}} \quad (2)$$

### 1. Trotter decomposition of time evolution operator [Schollwöck2011, Sec. 7.1.1]

General: write Hamiltonian as  $\hat{H} = \sum_l \hat{h}_l = \hat{H}_o + \hat{H}_e$  (3)

$\hat{h}_l$  connects sites  $l$  and  $l+1$       odd      even

Then all odd terms mutually commute, and all even terms mutually commute:

$$[\hat{h}_l, \hat{h}_{l'}] = 0 \quad \text{if } l, l' \text{ are both odd or both even} \quad (5)$$

Divide time interval into  $N$  slices:  $\beta = \tau N$  (6)

$$e^{-\beta \hat{H}} \stackrel{\text{Trotter decomposition}}{=} \left[ e^{-\tau \hat{H}} \right]^N = \left[ e^{-\tau (\hat{H}_o + \hat{H}_e)} \right]^N \quad (7)$$

$$\xrightarrow{N \rightarrow \infty, \tau \rightarrow 0} \simeq \left[ e^{-\tau \hat{H}_o} e^{-\tau \hat{H}_e} + \mathcal{O}(\tau^2) \right]^N \quad \text{'first order Trotter approx.'} \quad (8)$$

$$\text{or} \quad \simeq \left[ e^{-\frac{\tau}{2} \hat{H}_o} e^{-\tau \hat{H}_e} e^{-\frac{\tau}{2} \hat{H}_o} + \mathcal{O}(\tau^3) \right] \quad \text{'second order Trotter approx.'} \quad (9)$$

Exploiting (5), odd and even exponents can both be expanded separately without further approximation:

$$e^{-\tau \hat{H}_o} = e^{-\tau \hat{h}_1} e^{-\tau \hat{h}_3} \dots e^{-\tau \hat{h}_{L-1}} := \hat{U}_1 \hat{U}_3 \dots \hat{U}_{L-1} \quad (10a)$$

$$e^{-\tau \hat{H}_e} = e^{-\tau \hat{h}_2} e^{-\tau \hat{h}_4} \dots e^{-\tau \hat{h}_L} := \hat{U}_2 \hat{U}_4 \dots \hat{U}_L \quad (10b)$$

So, when applying  $e^{-\beta \hat{H}}$  to  $|\psi\rangle$ , we can successively apply all odd terms, then truncate, then all even ones, then truncate, etc.

$$e^{-\tau \hat{H}_e} e^{-\tau \hat{H}_o} |\psi\rangle = \text{Diagram (11)}$$

Diagram (11) shows a tensor network with two horizontal layers of blue circles. The top layer has red rectangular blocks labeled  $\hat{U}_1, \hat{U}_3, \hat{U}_4$  and orange rectangular blocks labeled  $\hat{U}_2$ . Vertical blue lines connect the circles between layers.

in MPO notation:

$$= \text{Diagram (12)}$$

Diagram (12) shows the same tensor network as (11) but with square MPO tensors. Red squares are labeled  $\hat{U}_1, \hat{U}_3$  and orange squares are labeled  $\hat{U}_2, \hat{U}_4$ . Horizontal lines connect the squares within each layer.

since  $\hat{H}_o$  factorizes, even bonds have dimension  $\chi_e = 1$

since  $\hat{H}_e$  factorizes, odd bonds have dimension  $\chi_o = 1$

All of this can be done for finite chain of length  $\mathcal{L}$ . But a simplification occurs for  $\mathcal{L} \rightarrow \infty$

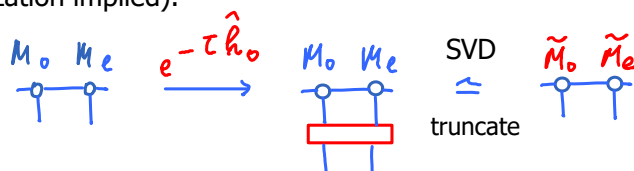

Then we can exploit translational invariance:

Adopt a two-site unit cell (no left- or right-normalization implied).

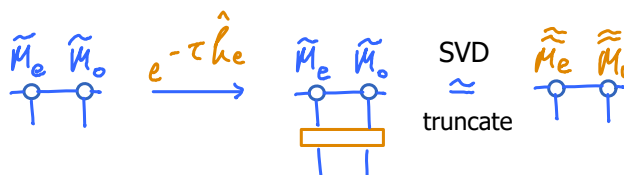

Step 1: time-evolve 'odd bond':

(first site odd, second site even)

Step 2: time-evolve (updated!) even bond:

(first site even, second site odd)

Iterate until convergence! (To discuss details, we will use  $\chi$  notation.)

iTEBD is a 'power method': the projector to the ground state is constructed as an increasing number of powers of  $e^{-\tau \hat{H}_e} e^{-\tau \hat{H}_o}$ .

This is to be contrasted to DMRG ground state search, which is a variational method.

Main advantage of iTEBD: costs not proportional to system size, hence comparatively cheap.

Main disadvantage: loss of orthogonality due to projection, without explicit reorthogonalization.

to be explained below

Usual bond-canonical form of MPS:

$$|\psi\rangle = |\Psi_\alpha\rangle_l |\Phi_\beta\rangle_{l+1} [S_l]^{\alpha\beta} \quad (1)$$

Choose  $S$  diagonal, and call it  $\Lambda$  (following Vidal):

$$|\psi\rangle = \sum_{\alpha} |\Psi_\alpha\rangle_l |\Phi_\alpha\rangle_{l+1} [\Lambda_l]^{\alpha\alpha} \quad (\text{Schmidt decomposition})$$

Then reduced density matrices of left and right parts are diagonal, with eigenvalues  $(\Lambda_l^{\alpha\alpha})^2$ :

$$\rho_L = \text{Tr}_R |\psi\rangle\langle\psi| = \sum_{\alpha} |\Psi_\alpha\rangle_l \underbrace{[\Lambda_l]^{\alpha\alpha} [\Lambda_l^\dagger]_{\alpha\alpha}}_{[\rho_{L,L}]^{\alpha}_{\alpha}} \langle\Psi_\alpha|$$

$$\rho_R = \text{Tr}_L |\psi\rangle\langle\psi| = \sum_{\alpha} |\Phi_\alpha\rangle_{l+1} \underbrace{[\Lambda_l^\dagger]_{\alpha\alpha} [\Lambda_l]^{\alpha\alpha}}_{[\rho_{R,R}]^{\alpha}_{\alpha}} \langle\Phi_\alpha|$$

Vidal introduced MPS representation in which Schmidt decomposition can be read off for each bond:

$$|\psi\rangle = \dots \underbrace{\Gamma_1 \Lambda_1 \Gamma_2 \Lambda_2 \dots \Gamma_l \Lambda_l \Gamma_{l+1}}_{\text{Schmidt decomposition}} \dots$$

where  $\Lambda_l$  = diagonal matrix, consisting of Schmidt coefficients for bond  $l$  between sites  $l$  and  $l+1$ :

$$|\psi\rangle = |\Psi_\alpha\rangle_l |\Phi_\alpha\rangle_{l+1} \Lambda_l^{\alpha\alpha}, \quad \rho_{L,L} := \Lambda_l \Lambda_l^\dagger = \Lambda_l^\dagger \Lambda_l =: \rho_{L,R}$$

with orthonormal sets on L:

$$\langle\Psi^{\alpha'}| \Psi_\alpha\rangle_l = \mathbb{1}^{\alpha'}_{\alpha} \quad (7)$$

and on R:

$$\langle\Phi^{\beta'}| \Phi_\beta\rangle_{l+1} = \mathbb{1}^{\beta'}_{\beta} \quad (8)$$

Any MPS can always be brought into  $\Gamma\Lambda$  form. Proceed in same manner as when left-normalizing, [cf. MPS-I.4]

$$|\psi\rangle = |\vec{\sigma}\rangle_l (M^{\sigma_1} \dots M^{\sigma_L})$$

Successively use SVD on pairs of adjacent tensors:

$$M M' = \underbrace{U}_A \underbrace{S V^\dagger}_{\tilde{M}} := A \tilde{M}, \quad (10)$$

to bring MPS into left-canonical form,

store singular values,  $\Lambda_\ell := S_\ell$  and at end define

$$\check{A}_\ell^{\sigma_\ell} := \check{\Lambda}_{\ell-1} \check{\Gamma}_\ell^{\sigma_\ell}, \quad \Lambda_0 = 1, \quad (11)$$

physical index  $\sigma_\ell$  of  $A_\ell$  is associated with  $\check{\Gamma}_\ell$

$$|\psi\rangle = \text{diagram with } A_1, A_2, \dots, A_\ell, A_L \text{ tensors} \quad (12)$$

$$=: \text{diagram with } \check{\Gamma}_1, \check{\Lambda}_1, \check{\Gamma}_2, \check{\Lambda}_2, \dots, \check{\Gamma}_\ell, \check{\Lambda}_{\ell-1}, \check{\Gamma}_L \text{ tensors} \quad (13)$$

Note: in numerical practice, this involves dividing by singular values,  $\check{\Gamma}_\ell^{\sigma_\ell} := \Lambda_{\ell-1}^{-1} A_\ell^{\sigma_\ell}$  (14)

So, first truncate states for which  $S_{\ell-1}^{\alpha\alpha} = 0$ , (15)

Even then, the procedure can be numerically unstable, since arbitrarily small singular values may arise.

So, truncate states for which (say)  $S_{\ell-1}^{\alpha\alpha} < 10^{-8}$ . In practice, this should be done in (16)

any case, because when computing norms and matrix elements, singular value  $s$  contributes weight  $s^2$  and when  $s^2 < 10^{-16}$ , its contribution gets lost in numerical noise. Inverting the remaining singular values,  $s > 10^{-8}$ , is unproblematic in numerical practice.

Similarly, if we start from the right, SVDs yield right-normalized  $B$ -tensors, and we can define

$$B_\ell^{\sigma_\ell} := \check{\Gamma}_\ell^{\sigma_\ell} \Lambda_\ell, \quad \Lambda_L = 1, \quad (17)$$

i.e.  $\check{\Gamma}_\ell^{\sigma_\ell} := B_\ell^{\sigma_\ell} \Lambda_\ell^{-1}$  (18)

So, relation between standard bond-canonical form and 'canonical  $\check{\Gamma}\Lambda$  form' is:

$$|\psi\rangle = \text{diagram with } A, \check{\Lambda}, B \text{ tensors} \quad (19)$$

$$1 = A_L^\dagger A_L = \check{\Gamma}_L^\dagger \Lambda_{L-1}^\dagger \Lambda_{L-1} \check{\Gamma}_L = \check{\Gamma}_L^\dagger \check{\Gamma}_{L-1, R} \check{\Gamma}_L, \quad \check{\Gamma} = \text{diagrammatic representation} \quad (20)$$

$$1 = B_L B_L^+ = \Gamma_L \Lambda_L \Lambda_L^+ \Gamma_L^+ = \Gamma_L \rho_{L,L} \Gamma_L^+ \quad , \quad \} = \begin{array}{c} \text{Diagram 1: } \Gamma_L \text{ (top), } \Lambda_L^+ \text{ (left), } \Gamma_L^+ \text{ (right), } \Lambda_L \text{ (bottom)} \\ \text{Diagram 2: } \Gamma_L \text{ (top), } \Lambda_L \text{ (left), } \Gamma_L^+ \text{ (right), } \Lambda_L^+ \text{ (bottom)} \\ \text{Diagram 3: } \Gamma_L \text{ (top), } \rho_{L,L} \text{ (left), } \Gamma_L^+ \text{ (right), } \rho_{L,L}^+ \text{ (bottom)} \end{array} \quad (21)$$

(20), (21) guarantee the orthonormality properties (7), (8)

If  $\Gamma_L$  has very small singular values,  $\Gamma_L$  must have large elements! Can lead to unstable behavior...

### 3. iTEBD: Explicit formulation

[Vidal2007], [Schollwöck2011, Sec. 10.4]

iTEBD.3

For infinite, translationally invariant system, use two-site unit cell,  $\begin{array}{c} M_o \quad M_e \\ \downarrow \quad \downarrow \\ \sigma_o \quad \sigma_e \end{array}$ , repeated periodically.

(to avoid cluttering,  $\sigma$  indices on  $\Lambda, A$  are not displayed, but implicitly understood)

Each iTEBD iteration involves two steps, updating first odd bonds, then even bonds:

1. update odd bonds:

$$|\psi\rangle = \dots \begin{array}{c} M_o \quad M_e \quad M_o \quad M_e \quad M_o \\ \downarrow \quad \downarrow \quad \downarrow \quad \downarrow \quad \downarrow \\ \sigma_o \quad \sigma_e \quad \sigma_o \quad \sigma_e \quad \sigma_o \end{array} \dots$$

$$:= \dots (\Lambda_e \Gamma_o) (\Lambda_o \Gamma_e) (\Lambda_e \Gamma_o) (\Lambda_o \Gamma_e) (\Lambda_e \Gamma_o) \dots$$

yields new  $\tilde{\Lambda}_o, \tilde{\Lambda}_e, \tilde{\Gamma}_e$  insert these throughout chain but leave  $\Lambda_e$  unchanged (2a)

2. update even bonds:

$$\dots (\Lambda_e \tilde{\Gamma}_o \tilde{\Lambda}_o \tilde{\Gamma}_e \Lambda_e) \tilde{\Gamma}_o \tilde{\Lambda}_o \tilde{\Gamma}_e \Lambda_e \tilde{\Gamma}_o \dots$$

yields new  $\tilde{\tilde{\Gamma}}_e, \tilde{\tilde{\Lambda}}_e, \tilde{\tilde{\Gamma}}_o$  insert these throughout chain but leave  $\tilde{\Lambda}_o$  unchanged (2b)

Then rename  $\tilde{\Lambda}_{o,e} \rightarrow \Lambda_{o,e}$ ,  $\tilde{\Gamma}_{o,e} = \Gamma_{o,e}$ , and iterate.

Step 1: Time-evolve odd bond  $\Gamma_o \Lambda_o \Gamma_e$  and its environment  $\Lambda_e \dots \Lambda_e$

$$\hat{U}_o := e^{-\tau \hat{h}_o} = \begin{array}{c} \uparrow \bar{\sigma}_o \quad \uparrow \bar{\sigma}_e \\ \hline \uparrow \sigma_o \quad \uparrow \sigma_e \end{array} \quad (3)$$

contract, reshape, = SVD

truncate, normalize [see (7)]

reshape

define  $\tilde{\Gamma}_o := \Lambda_e^{-1} \tilde{A}_o$   
 $\tilde{\Gamma}_e := \tilde{B}_e \Lambda_e^{-1}$

left-normalized  $\tilde{A}_o$   $\tilde{B}_e$  right-normalized

restate  $\Lambda_e$

define  $\tilde{\tilde{M}}_e := \tilde{\Lambda}_o \tilde{\tilde{\Gamma}}_e = \tilde{\Lambda}_o \tilde{B}_e \Lambda_e^{-1}$

left-normalized  $\tilde{\tilde{A}}_o$   $\tilde{\tilde{M}}_e$  not right-normalized

$\hat{U}_o$  is "projector" (not unitary operation), hence reduces norm. Thus,  $\tilde{\Lambda}_o$  is normalized to unity by hand:

$$\tilde{\Lambda}_o := \frac{S_{\text{trunc}}}{[\text{Tr}(S_{\text{trunc}}^\dagger S_{\text{trunc}})]^{1/2}}, \text{ then } \begin{array}{c} \tilde{\tilde{A}}_o \quad \tilde{\tilde{\Lambda}}_o \quad \tilde{\tilde{B}}_e \\ \downarrow \quad \downarrow \quad \downarrow \\ \tilde{\tilde{\Lambda}}_o^\dagger \quad \tilde{\tilde{\Lambda}}_o \quad \tilde{\tilde{B}}_e^\dagger \end{array} = \begin{array}{c} \tilde{\tilde{\Lambda}}_o \\ \downarrow \\ \tilde{\tilde{\Lambda}}_o^\dagger \end{array} = \text{Tr} \tilde{\tilde{\Lambda}}_o^\dagger \tilde{\tilde{\Lambda}}_o = 1 \quad (7)$$

(6) completes update of odd bond. The updated MPS now has the form  $|\tilde{\psi}\rangle \stackrel{(6)}{=} \prod_{\sigma} \tilde{\tilde{A}}_o \tilde{\tilde{M}}_e \tilde{\tilde{A}}_o \tilde{\tilde{M}}_e \dots \stackrel{(8)}{=}$

$$\Lambda_o := \frac{\text{trunc}}{[\text{Tr}(S_{\text{trunc}}^\dagger S_{\text{trunc}})]^{1/2}}, \text{ then } \left( \begin{array}{c} \text{---} \text{---} \text{---} \\ \tilde{\Lambda}_o^\dagger \quad \tilde{\Lambda}_o^\dagger \quad \tilde{\Lambda}_e^\dagger \end{array} \right) = \left( \begin{array}{c} \text{---} \\ \tilde{\Lambda}_o^\dagger \end{array} \right) = \text{Tr} \tilde{\Lambda}_o^\dagger \Lambda_o = 1 \quad (7)$$

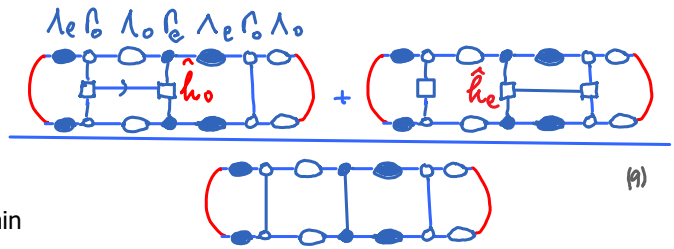

(6) completes update of odd bond. The updated MPS now has the form  $|\tilde{\psi}\rangle \stackrel{(6)}{=} \prod_{\sigma} \tilde{A}_o \tilde{M}_e \tilde{A}_o \tilde{M}_e \dots \quad (8)$

Updated bond energy :

$$\bar{h}_{\text{bond}} = \frac{1}{2}(\bar{h}_o + \bar{h}_e) \approx$$

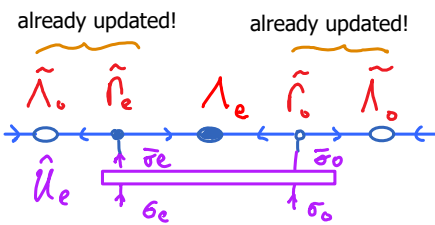

consider only two sites

ignore tensors describing rest of chain

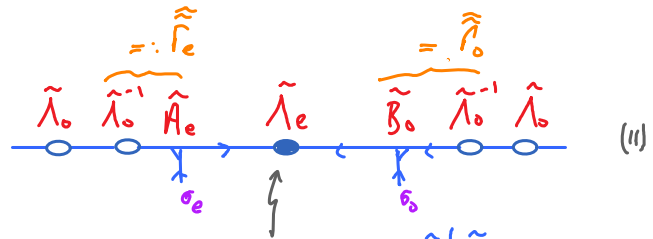

Updating odd bond lowers  $\bar{h}_o$ , slightly raises  $\bar{h}_e$  ('odd bond much happier, even bond slightly unhappier').

Step 2: Time-evolve even bond  $\tilde{\Lambda}_e \Lambda_e \tilde{\Lambda}_o$  and its environment  $\tilde{\Lambda}_o \dots \tilde{\Lambda}_o$   $\hat{U}_e := e^{-\tau \hat{h}_e} = \begin{array}{c} \uparrow \tilde{\sigma}_e \quad \uparrow \tilde{\sigma}_o \\ \text{---} \\ \uparrow \tilde{\sigma}_e \quad \uparrow \tilde{\sigma}_o \end{array} \quad (10)$

contract, reshape, SVD, reshape, truncate, normalize, reinstate

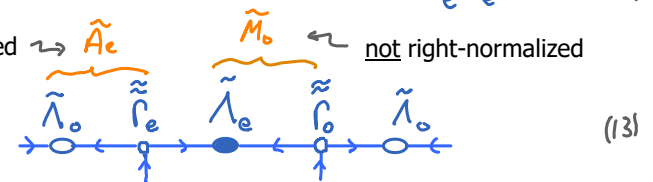

with normalization  $\text{Tr} \tilde{\Lambda}_e^\dagger \tilde{\Lambda}_e = 1 \quad (12)$

define

$$\begin{aligned} \tilde{\Lambda}_e &:= \tilde{\Lambda}_o^{-1} \tilde{A}_e \\ \tilde{\Lambda}_o &:= \tilde{B}_o \tilde{\Lambda}_o^{-1} \\ \tilde{M}_o &:= \tilde{\Lambda}_e \tilde{\Lambda}_o = \tilde{\Lambda}_e \tilde{B}_o \tilde{\Lambda}_o^{-1} \end{aligned}$$

left-normalized  $\tilde{A}_e$

not right-normalized

(13)

(12) completes update of even bond. Updated MPS now has the form  $|\tilde{\psi}\rangle = \prod_{\sigma} |\tilde{\sigma}\rangle \tilde{M}_o \tilde{A}_e \tilde{M}_o \tilde{A}_e \dots \quad (14)$

Compute updated bond energy using (9), with  $o \leftrightarrow e$ .

Updating even bond lowers  $\bar{h}_e$ , slightly raises  $\bar{h}_o$  ('even bond much happier, odd bond slightly unhappier').

Now iterate: rename  $\tilde{M}_{o,e} \rightarrow M_{o,e}$ ,  $\tilde{\Lambda}_{o,e} \rightarrow \Lambda_{o,e}$ ,  $\tilde{\Lambda}_{o,e} \rightarrow \Gamma_{o,e}$

then apply  $\hat{U}_o$ , then  $\hat{U}_e$ , etc.) until convergence is reached (monitor ground state energy...)

Remarks:

1. In principle, computation of  $\tilde{\Lambda}_o^{-1}$ ,  $\tilde{\Lambda}_e^{-1}$  can become unstable, because singular values can be very small. Thus: truncate by discarding smallest singular values  $\approx 10^{-8}$ , only then invert.

2. Note that  $\tilde{A}_o$  is left-normalized, but  $\tilde{M}_e \stackrel{(6,5)}{=} \tilde{\Lambda}_o \tilde{B}_e \tilde{\Lambda}_e^{-1}$  is not! 'Loss of orthogonality'.  
 $\tilde{M}_o \stackrel{(13,11)}{=} \tilde{\Lambda}_e \tilde{B}_o \tilde{\Lambda}_o^{-1}$

This causes problems when computing expectation values. For example, odd bond energy, given by

$$\begin{array}{c}
 \dots \quad M_e \quad A_o \quad M_e \quad H_o \quad M_e \quad H_o \quad M_e \quad A_o \quad \dots \\
 \hline
 \dots \quad \text{[Diagram of a chain with a zipper-like structure]} \quad \dots
 \end{array}
 \quad / \quad
 \begin{array}{c}
 M_e \quad A_o \quad M_e \quad A_o \quad M_e \quad A_o \quad M_e \quad A_o \quad \dots \\
 \hline
 \dots \quad \text{[Diagram of a chain with a zipper-like structure]} \quad \dots
 \end{array}
 \quad (15)$$

does not reduce to (9), because zippers can not be closed from left and right. Hence (9) involves an approximation, namely ignoring the rest of the chain.

## iTEBD.4

[Hastings2009, Sec. II.A], [Schollwöck2011, Sec. 7.3.2]

Goal: avoid 'reinstatement' of  $\lambda_e, \lambda_o$ , since this requires inverting singular-value matrix.  
(i.e. dividing by small singular values)

Write  $(14) =$

The diagram shows a horizontal chain of sites and bonds. Sites are represented by circles, some filled (blue) and some empty (white). Bonds are represented by arrows between sites. Brackets above the chain group sites into pairs:  $M_o$  (filled, empty),  $M_e$  (empty, filled), and  $M_o$  (filled, empty). Brackets below the chain group bonds into pairs:  $\beta_o$  (empty to filled),  $\beta_e$  (filled to empty), and  $\beta_o$  (empty to filled). A green bracket at the bottom labels the first bond as 'odd bond' and the subsequent two as 'even bond'.

(i)

with  $M_0 = \Lambda_e \Gamma_0$ ,  $M_e = \Lambda_0 \Gamma_e$ ,  $B_0 = \Gamma_0 \Lambda_0$ ,  $B_e = \Gamma_e \Lambda_e$  (2)

Step 1: Time-evolve odd bond  $M_o, \Lambda_o, B_e$  to define  $\hat{A}_o, \hat{\Lambda}_o, \hat{B}_x$  via SVD, and  $\tilde{M}_e$  via contraction.  
(instead of reinstatement of  $\Lambda_e$ )

Step 2: Time-evolve even bond  $\tilde{M}_e \Lambda_e B_o$  to define  $\tilde{A}_e \tilde{\Lambda}_e \tilde{B}_o$  via SVD, and  $\tilde{M}_o$  via contraction.  
(instead of reinstatement of  $\tilde{\Lambda}_o$ )

Then rename  $\tilde{M}_{o,e} \rightarrow M_{o,e}$ ,  $\tilde{\Lambda}_{o,e} \rightarrow \Lambda_{o,e}$ ,  $\tilde{B}_{o,e} = B_{o,e}$ , and iterate.

Step 1 (odd-even): Compute

known from initialization,  
or previous iteration ↗

left-normalized

$$T_r \tilde{\Lambda}_0^\dagger \tilde{\Lambda}_0 = I$$

right-normalized

Do SVD on  $\Phi_0 \Lambda_e$  =  SVD =:  (4)

SVD yields updated tensors  $\tilde{A}_o, \tilde{\Lambda}_o, \tilde{B}_e$ . Note that the outgoing leg of  $\tilde{A}_o$  involves a truncation, governed by  $\tilde{\Lambda}_o$ . Since this is also the incoming leg of what will be called  $\tilde{M}_e$ , we need a definition of the latter involving a truncation governed by  $\tilde{\Lambda}_o$  on its incoming leg. This is achieved by left-contraction with  $\tilde{A}_o^\dagger$ :

$$\tilde{M}_e^{\sigma_e} := \tilde{A}_{\sigma_0}^{\dagger} \Phi_{\sigma_0}^{\sigma_0 \sigma_e} \quad [\text{symbol } M \text{ denotes: not left-normalized, see (7)}] \quad (5)$$

(Note: no inversion of singular matrix required!) Justification for this definition:

(Note: no inversion of singular matrix required!) Justification for this definition:

(3)

(4)

(5)

(6)

(7)

$\hat{A}_{\sigma_0 \sigma_e}^\dagger \Phi_{\sigma_0 \sigma_e} = \mathbb{1}$

not left-normalized

$$\tilde{A}_o^T \tilde{A}_o^{\sigma_o} = 1 \quad = \quad \text{diagram (5)} \quad =: \quad \text{diagram (7)} \quad (7)$$

where we associated  $\tilde{\Lambda}_e := \tilde{B}_e \Lambda_e^{-1}$  and  $\tilde{M}_e := \tilde{\Lambda}_o \tilde{\Gamma}_e$  by analogy to (2) [but did not need  $\Lambda_e^{-1}$  explicitly!] (8)

This concludes step 1. We now have updated tensors

$$M_o \rightarrow \tilde{A}_o, \quad \Lambda_o \rightarrow \tilde{\Lambda}_o, \quad B_e \rightarrow \tilde{B}_e, \quad M_e \rightarrow \tilde{M}_e, \quad \text{but not updated } \Lambda_e, B_o$$

Step 2 (even-odd): Compute

$$\hat{U}_e \quad \text{diagram} \quad =: \quad \text{diagram} \quad =: \quad \Phi_e^{\sigma_e \sigma_o} \quad (9)$$

known from step 1:

Do SVD on  $\Phi_e^{\sigma_e \sigma_o} \tilde{\Lambda}_o$  =  $\text{diagram}$  SVD =:  $\text{diagram}$  (10)

left-normalized  $\tilde{\Lambda}_e^+ \tilde{\Lambda}_e = 1$  right-normalized  $\tilde{\Lambda}_e \tilde{\Lambda}_e^+ = 1$

$\tilde{M}_o \tilde{\Lambda}_o$

The SVD yields updated tensors  $\tilde{A}_e, \tilde{\Lambda}_e, \tilde{B}_o$ , and  $\tilde{A}_e$  has a  $\tilde{\Lambda}_e$  truncation on its outgoing leg, i.e. incoming leg of what will be called  $\tilde{M}_o$ , so we need a definition of the latter with  $\tilde{\Lambda}_e$  on incoming leg:

This is achieved by:

$$\tilde{M}_o^{\sigma_o} := \tilde{A}_e^+ \Phi_e^{\sigma_e \sigma_o} \quad [\text{not left-normalized, see (12)}] \quad (11)$$

Justification:

$$\tilde{A}_e^+ \Phi_e^{\sigma_e \sigma_o} \quad (9) \quad = \quad \text{diagram} \quad (10) \quad = \quad \text{diagram} \quad (12) \quad =: \quad \tilde{M}_o \quad (12)$$

not left-normalized

where we associated  $\tilde{\Gamma}_o := \tilde{B}_o \tilde{\Lambda}_o^{-1}$  and  $\tilde{M}_o := \tilde{\Lambda}_e \tilde{\Gamma}_o$  by analogy to (2) [but did not need  $\tilde{\Lambda}_o^{-1}$  explicitly!] (13)

This concludes step 2. We now have updated tensors

$$\tilde{M}_e \rightarrow \tilde{A}_e, \quad \Lambda_e \rightarrow \tilde{\Lambda}_e, \quad B_o \rightarrow \tilde{B}_o, \quad M_o \rightarrow \tilde{M}_o \quad \text{without changing } \tilde{\Lambda}_o, \tilde{B}_e$$

Now iterate (apply  $\hat{U}_o$ , then  $\hat{U}_e$ , etc.) until convergence of bond energy is reached.

Compute bond energy using (iTEBD3.9) for step 1, or its  $o \leftrightarrow e$  version for step 2.

Concluding remarks:

Main advantage of iTEBD: costs not proportional to system size, hence comparatively cheap.

Main disadvantage: loss of orthogonality due to projection, without explicit reorthogonalization.

Needed for computing correlators via transfer matrix.

Definition: an infinite, translationally invariant MPS with two-site unit cell, expressed in the form [Orus2008]

$|4\rangle =$

In this section, we use open or closed triangles, or , for odd or even isometries.

is called 'two-site canonical' if  $A_{0,e}$  are left-normalized and  $B_{0,e}$  are right-normalized:

[illegible]

Correlators can then be computed using transfer matrix methods:

$$\langle \hat{O}_l \hat{O}_{l'} \rangle = \dots \begin{array}{c} A_o \quad A_e \quad A_o \quad A_e \quad A_o \quad A_e \quad A_o \quad A_e \quad A_o \quad B_e \quad B_o \quad B_e \quad B_o \quad \dots \\ \hline \begin{array}{c} \square \\ O_l \end{array} \quad \begin{array}{c} \square \\ O_{l'} \end{array} \quad \dots \end{array} \quad (2)$$

close zippers

ii

(3)

Problem: iTEBD (including Hastings' version) yields infinite MPS that are not in canonical form, due to loss of orthogonality. It is possible to restore orthogonality (albeit at the cost of inverting singular value matrices).

Strategy: given  $\{\rho_e, \lambda_e, \rho_o, \lambda_o\}$  :  
2-site unit cell

Step 1: 'coarse-grain' to get  $\{\Gamma, \Lambda\}$  :  
 $\Gamma := c_e \Lambda_e \Gamma_o$  ,  $\Lambda := \Lambda_o$  1-site unit cell

Step 2: bring into 1-site canonical form  $\{\tilde{\rho}, \tilde{\lambda}\}$  :  
 1-site unit cell

(a)

(b)

(how? will be explained further below)

Definition of 1-site canonical:

$$\tilde{\Lambda}^2 := \begin{array}{c} \tilde{\Lambda} \\ \downarrow \\ \tilde{\Lambda}^\dagger \end{array} = \tilde{\Lambda}$$

1-site unit cell

$$\tilde{\Lambda}^2 = \uparrow \quad (6a)$$

$$\tilde{\Lambda}^2 = \uparrow \quad (6b)$$

Step 3: 'fine-grain' via SVD,

reinststate

$$\tilde{\Lambda}_o := \tilde{\Lambda}$$

$$\tilde{\Lambda} \tilde{\Gamma} \tilde{\Lambda} \quad \text{SVD}$$

reinststate

left-canonical

right-canonical

$$\tilde{\Lambda}_o \tilde{\Lambda}_o^{-1} \tilde{A}_e \tilde{\Lambda}_e \tilde{B}_o \tilde{\Lambda}_o^{-1} \tilde{\Lambda}_o \quad (7)$$

$$\tilde{\Lambda}_o \tilde{\Gamma}_e \tilde{\Lambda}_o \tilde{\Gamma}_o \tilde{\Lambda}_o \quad (8)$$

define  $\{\tilde{\Gamma}_e, \tilde{\Lambda}_e, \tilde{\Gamma}_o, \tilde{\Lambda}_o\}$   
2-site unit cell

$$\text{with } \tilde{\Lambda}_o := \tilde{\Lambda} \quad (9a),$$

$$\tilde{\Lambda}_o \tilde{\Gamma}_e \tilde{\Lambda}_o := \tilde{A}_e \quad (9b),$$

$$\tilde{\Gamma}_o \tilde{\Lambda}_o := \tilde{B}_o \quad (9c),$$

$$\tilde{\Gamma}_e \tilde{\Lambda}_e \tilde{\Gamma}_o = \tilde{\Gamma} \quad (9d)$$

Claim:  $\{\tilde{\Gamma}_e, \tilde{\Lambda}_e, \tilde{\Gamma}_o, \tilde{\Lambda}_o\}$  constructed in this manner (via (6)), is in the desired 2-site canonical form.

Proof: Since  $\tilde{A}_e$  and  $\tilde{B}_o$  were obtained via SVD, they are left- and right-normalized, respectively. Hence:

$$\tilde{\Lambda}_o^2 \tilde{\Gamma}_e \tilde{\Lambda}_o = \tilde{\Lambda}_o \tilde{\Gamma}_e \tilde{\Lambda}_o \tilde{\Lambda}_o^\dagger = \tilde{\Lambda}_o \tilde{\Gamma}_e \tilde{\Lambda}_o \quad (10a) \quad \checkmark \quad \text{as required by (3b)}$$

$$\tilde{\Gamma}_o \tilde{\Lambda}_o^2 \tilde{\Gamma}_o = \tilde{\Gamma}_o \tilde{\Lambda}_o \tilde{\Gamma}_o \tilde{\Lambda}_o^\dagger = \tilde{\Gamma}_o \tilde{\Lambda}_o \tilde{\Gamma}_o \quad (10b) \quad \checkmark \quad \text{as required by (3c)}$$

Moreover:

$$\tilde{\Lambda}_e \tilde{\Gamma}_e \tilde{\Lambda}_e = \tilde{\Lambda}_e \tilde{\Gamma}_e \tilde{\Lambda}_e \tilde{\Lambda}_e^\dagger = \tilde{\Lambda}_e \tilde{\Gamma}_e \tilde{\Lambda}_e \quad (11a) \quad \checkmark \quad \text{Eq. (6) was assumed to hold when constructing } \{\tilde{\Gamma}_e, \tilde{\Lambda}_e, \tilde{\Gamma}_o, \tilde{\Lambda}_o\}$$

and:

$$\tilde{\Gamma}_o \tilde{\Lambda}_o \tilde{\Gamma}_o = \tilde{\Gamma}_o \tilde{\Lambda}_o \tilde{\Gamma}_o \tilde{\Lambda}_o^\dagger = \tilde{\Gamma}_o \tilde{\Lambda}_o \tilde{\Gamma}_o \quad (11b) \quad \checkmark$$

Back to step 2: How to bring arbitrary  $\{\Gamma, \Lambda\}$  into 1-site canonical form  $\{\tilde{\Gamma}, \tilde{\Lambda}\}$ :

not 1-site canonical

Starting point:

(henceforth we draw single line for double physical index)

$$\begin{array}{c} \uparrow \\ \downarrow \\ \Gamma \end{array} \neq \uparrow \quad (12)$$

Thus, corresponding 'transfer matrices' are not normalized:

$$\begin{array}{c} R \\ \downarrow \\ \Gamma \end{array} = \begin{array}{c} \Gamma \\ \downarrow \\ \Gamma^\dagger \end{array}, \quad \begin{array}{c} R \\ \downarrow \\ \Gamma \end{array} \neq \uparrow, \quad \begin{array}{c} L \\ \downarrow \\ \Lambda \end{array} = \begin{array}{c} \Lambda \\ \downarrow \\ \Lambda^\dagger \end{array}, \quad \begin{array}{c} L \\ \downarrow \\ \Lambda \end{array} \neq \uparrow \quad (13)$$

Def: if  $M$  is hermitian and positive semidefinite, its 'principal square root' satisfies  $M^{1/2} M^{1/2} = M$  and  $M^{1/2 \dagger} = M^{1/2}$ .

To construct  $M^{1/2}$ , diagonalize  $M = W D W^\dagger = \underbrace{W D^{1/2} W^\dagger}_{M^{1/2}} \underbrace{D^{1/2}}_{M^{1/2}}$  and define  $M^{1/2} = W D^{1/2} W^\dagger$ . (14)

The principal square root hermitian, positive semidefinite, and unique.

$$\begin{aligned}
 \text{largest eigenvalue} \quad & \text{Diagram (15a)}: \text{A square loop with red diagonal lines and a red square on the right side.} \\
 & \text{Diagram (15b)}: \text{A square loop with orange diagonal lines and an orange square on the right side.} \\
 & \text{Diagram (15c)}: \text{A square loop with red diagonal lines and a red square on the right side.} \\
 & \text{Diagram (15d)}: \text{A square loop with orange diagonal lines and an orange square on the right side.}
 \end{aligned}$$

Then

(16a)  $\text{Diagram with } X^{-1} \text{ and } X^{-1\dagger} \text{ on external legs and } X \text{ on internal legs} = \text{Diagram with } \eta \text{ on internal legs}$

(16b)  $\text{Diagram with } Y^{-1} \text{ and } Y^{-1\dagger} \text{ on external legs and } Y \text{ on internal legs} = \text{Diagram with } \eta \text{ on internal legs}$

[to cancel factors of  $X$  and  $Y$  when computing normalization in (15)]

Claim:  $\{ \tilde{V}, \tilde{U} \}$  is in the desired 2-site canonical form.

Proof: Since  $U$  and  $V^\dagger$  were obtained via SVD, they satisfy

$$U^\dagger U = \mathbb{1} \quad (20a)$$

$$V^\dagger V = \mathbb{1} \quad (20b)$$

Hence
